Introduction

- Sensitivity Analysis (SA) is useful to identify influential parameters in model calibration.
- Problem: lack of formal procedures and few examples of SA in the calibration of microscopic traffic models, especially computationally expensive models.
- Our aim: to develop an efficient approach as a preliminary screening tool.

Review of SA Methods

SVT

Introduction

Quasi-OTEE Method

Case Study

Conclusions

- Derivative-based approach
- Regression-based approach
- Sampling-based approach
- Variance-based approach
- Metamodel-based approach
- Monte Carlo Filtering approach
- Screening approach: *Elementary Effects Method*

Definition of Elementary Effect

A model Y has k parameters $\mathbf{X} = [X_1, X_2, \dots, X_k]$, the output is:

$$Y(\mathbf{X}) = Y(X_1, \dots, X_{i-1}, X_i, \dots, X_k)$$

If X_i is changed by Δ , then the EE is:

$$EE_i = \frac{Y(X_1, \dots, X_{i-1}, X_i + \Delta, \dots, X_k) - Y(X_1, \dots, X_{i-1}, X_i, \dots, X_k)}{\Delta}$$

with $i \in [1, 2, 3, \dots, k]$

Calculating the Sensitivity Index (SI) μ , μ^* and σ of EE by sampling different \mathbf{X} :

- 1) Non-influential parameters: low μ^*
- 2) Linear and additive effects, no interaction: high μ^* but low σ
- 3) Non-linear effects and/or strong interactions: high μ^* and σ
- 4) Oscillating effects: low μ but high μ^*

Sampling Strategy (1/2)

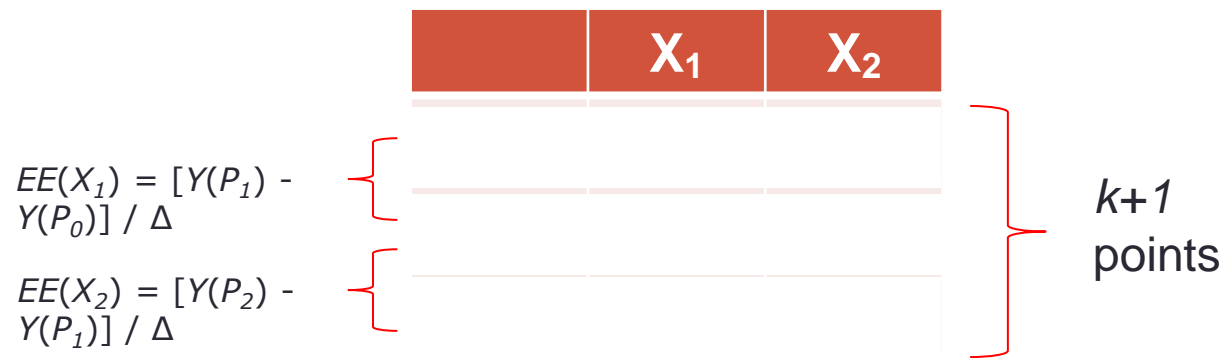

- Two model runs are required to calculate one EE for X_i : with initial inputs $[X_1, X_2, \dots, X_{i-1}, X_i, X_{i+1}, \dots, X_k]$ and the varied inputs $[X_1, X_2, \dots, X_{i-1}, X_i + \Delta, X_{i+1}, \dots, X_k]$.
- A k -parameter model: if m EEs are required for each parameter, then **$2mk$** model runs are required.

e.g. $k=14$, $m=200$, 30 min/run
Total computation time \approx 116 days

Sampling Strategy (2/2)

A model with 2 parameters $[X_1, X_2]$

$k+1$ points = one **trajectory**

If randomly sampling m trajectories, same results only need $m(k+1)$ runs.

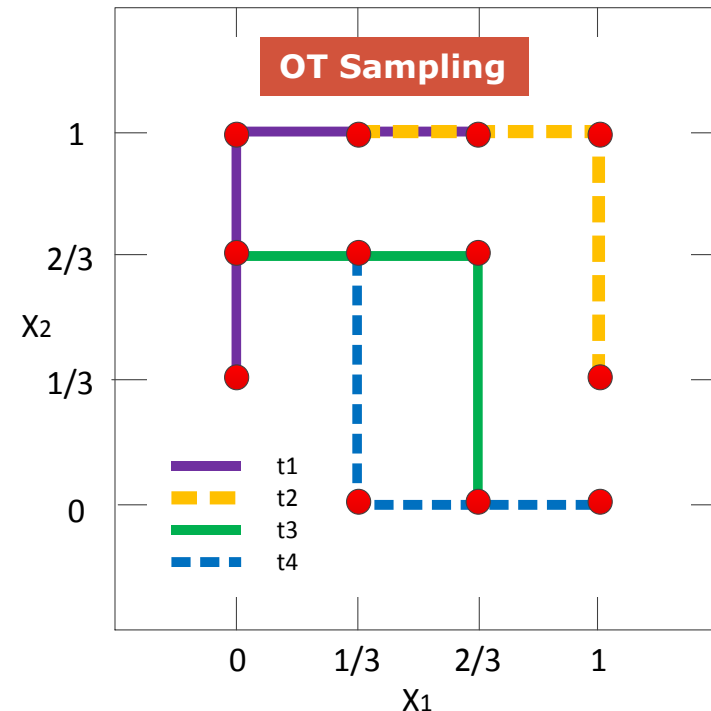

e.g. $k=14$, $m=200$, 30 min/run
Total computation time \approx 62 days

Optimized Trajectories (1/2)

Solution:

Find an optimized set of trajectories (OT) that covers the total input space as much as possible.

● = Sample Point

Optimized Trajectories (2/2)

1. Randomly generate m trajectories
2. Enumerate all possible sets containing n trajectories from the original m random trajectories ($n \ll m$)
3. Pick the set with the highest dispersion

Source: Campolongo et al., 2006

e.g. $k = 14$, $n = 10$, 30 min/run
Total computation time for EE \approx 3 days

Problem of the Original OT Sampling

SVT

Introduction

Quasi-OTEE Method

Case Study

Conclusions

However:

when m is large, the total number of combinations could be huge!

$$N = \frac{m!}{n! * (m-n)!}$$

e.g. $m = 200$, $n = 10$, $N \approx 2 \times 10^{16}$

Computation time for enumerating ≈ 50 days

Quasi-Optimized Trajectories

Step 1: Pick the optimized set (i.e., S_1) of $m - 1$ trajectories from the original set (i.e., S_0 , containing m trajectories)

Step 2: Pick the optimized set (i.e., S_2) of $m - 2$ trajectories based on S_1

.....

Step $m-n$: only n trajectories are left

$$\text{Total combinations} = m + (m - 1) + \dots + n = \frac{(m+n)(m-n+1)}{2} \ll \frac{m!}{n! \cdot (m-n)!} .$$

Note: the trajectories may not always be identical to the ones found by the original OT approach, so we call them the quasi-OT

e.g. $m=200$, $n=10$, $N=20,055$

Computation time for enumerating ≈ 15 min

OT Sampling V.S. Quasi-OT Sampling

SVT

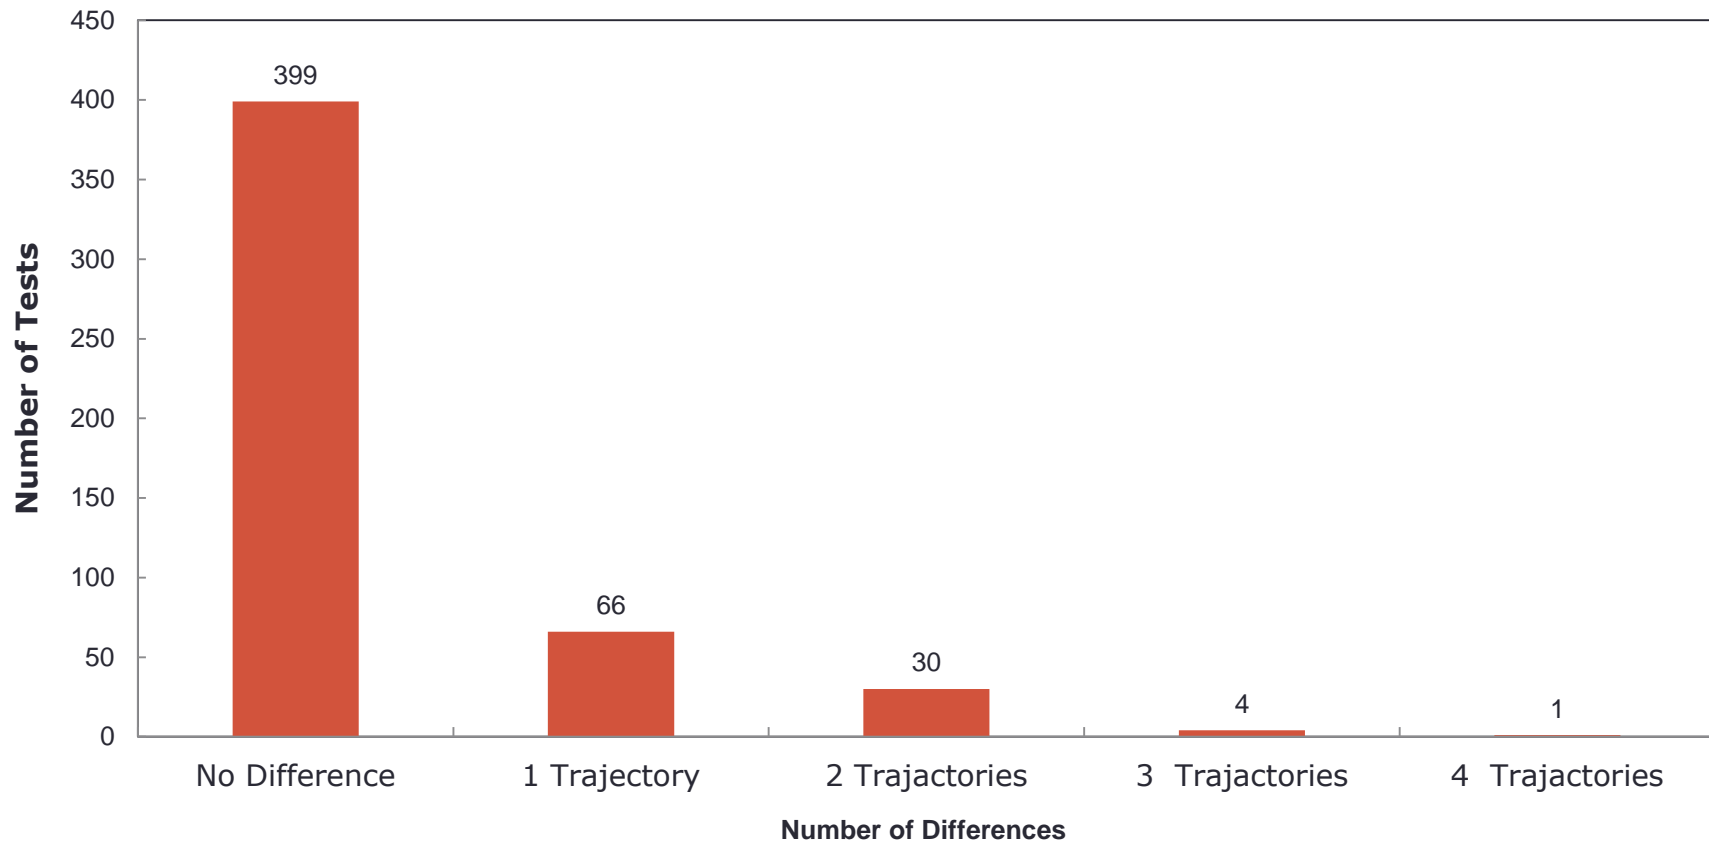

Introduction

Quasi-OTEE Method

Case Study

Conclusions

500 tests of selecting 10 OT / quasi-OT from 20 randomly generated trajectories

Review of Progress

SVT

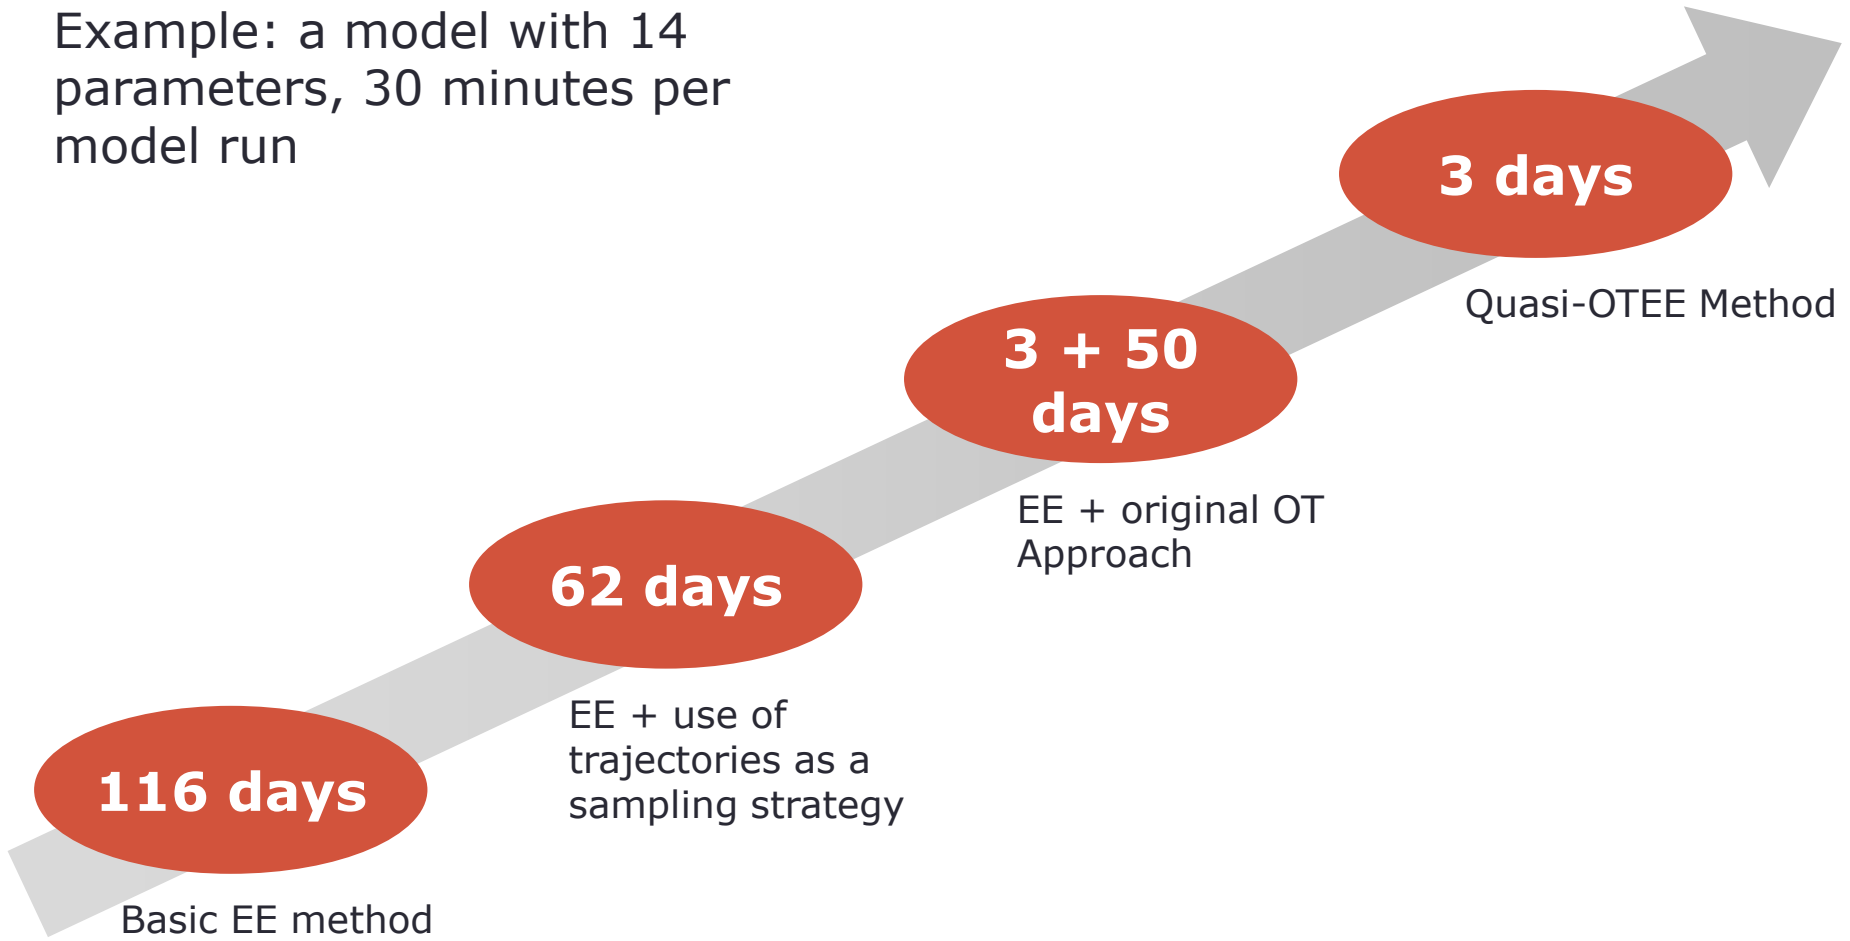

Introduction

Quasi-OTEE Method

Case Study

Conclusions

Example: a model with 14 parameters, 30 minutes per model run

Case Background

Introduction

Quasi-OTEE Method

Case Study

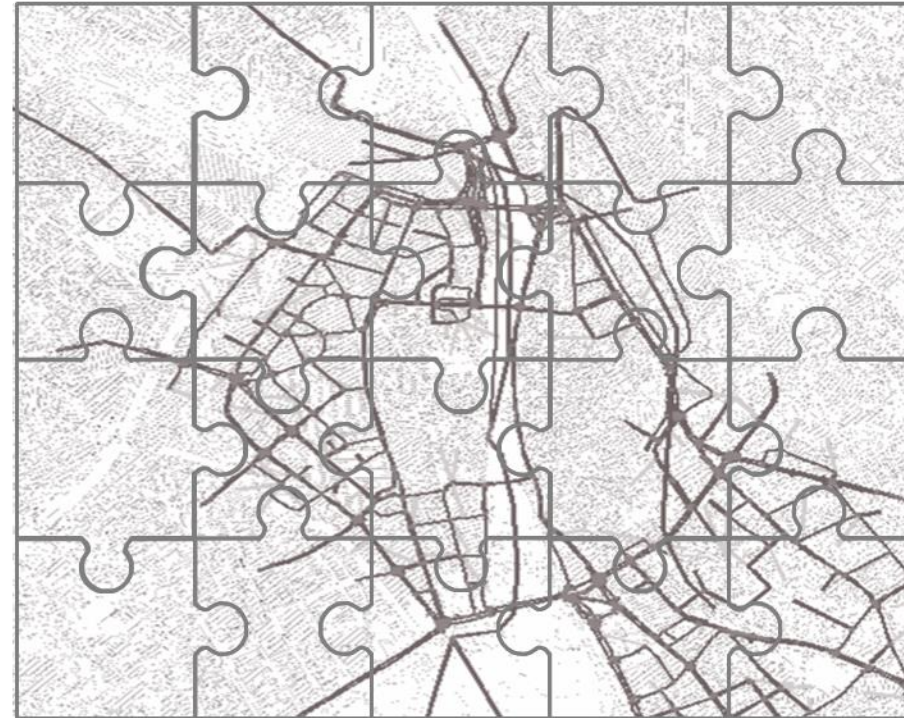

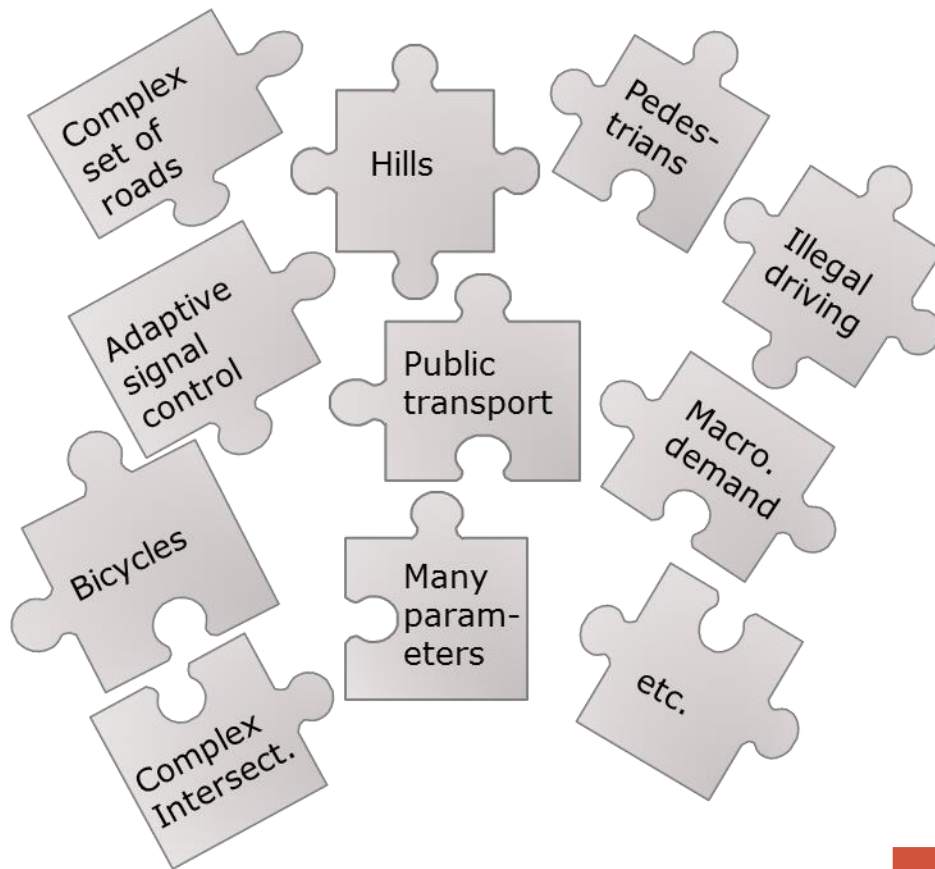

Conclusions

SVT

- Study area in VISSIM: inner city of Zurich (around 2.6 km²)
- Simulation period: 5pm to 6pm
- Warm up period: 900 simulation seconds
- Aim of SA: to identify the parameters with the highest influence on travel time

Challenges of the SA

- **192 VISSIM parameters**
- **VISSIM model is complicated and behaves like a black box**
- **Computational cost is very high (> 30 min per simulation run)**

Pre-selection of Parameters (1/2)

Introduction

Quasi-OTEE Method

Case Study

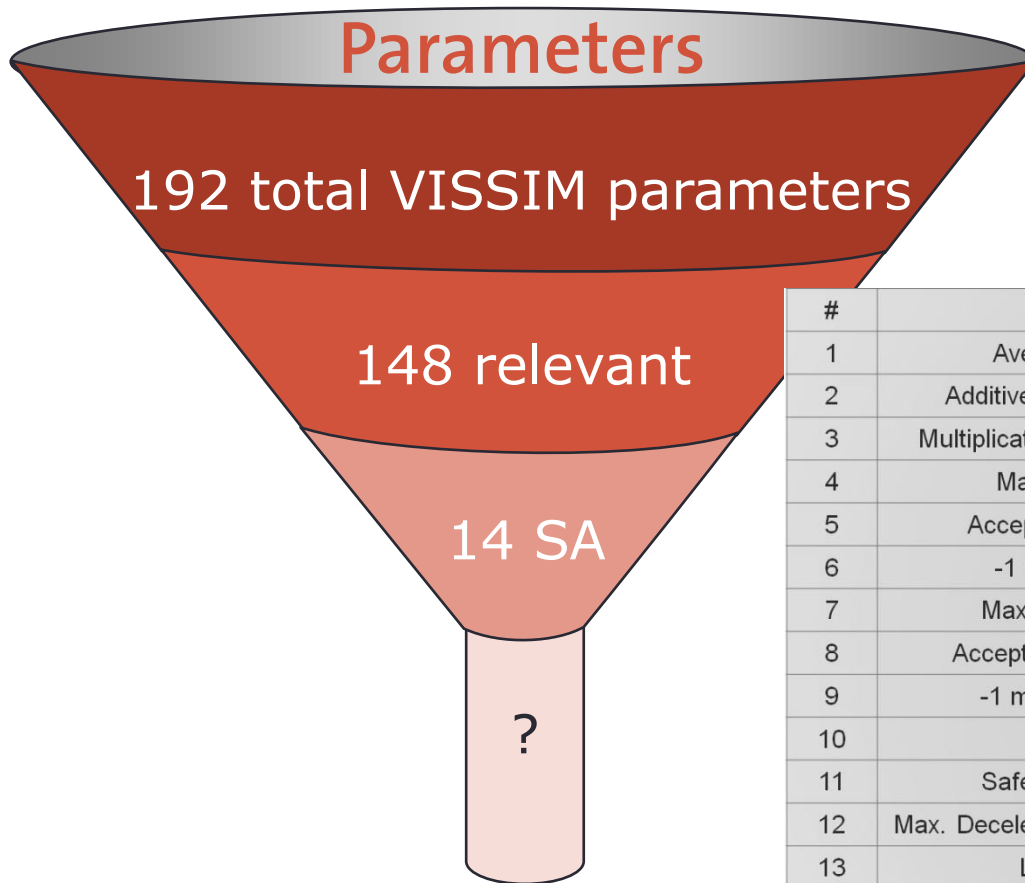

Conclusions

#	#	Parameter	Relevance			
			Very Important, need calibration	Relevant, use the value from Demand Model and VISSUM output	Relevant, use VISSIM default value	Not relevant

Each parameter was analyzed individually, and categorized according to its relevance within the Zurich model

Pre-selection of Parameters (2/2)

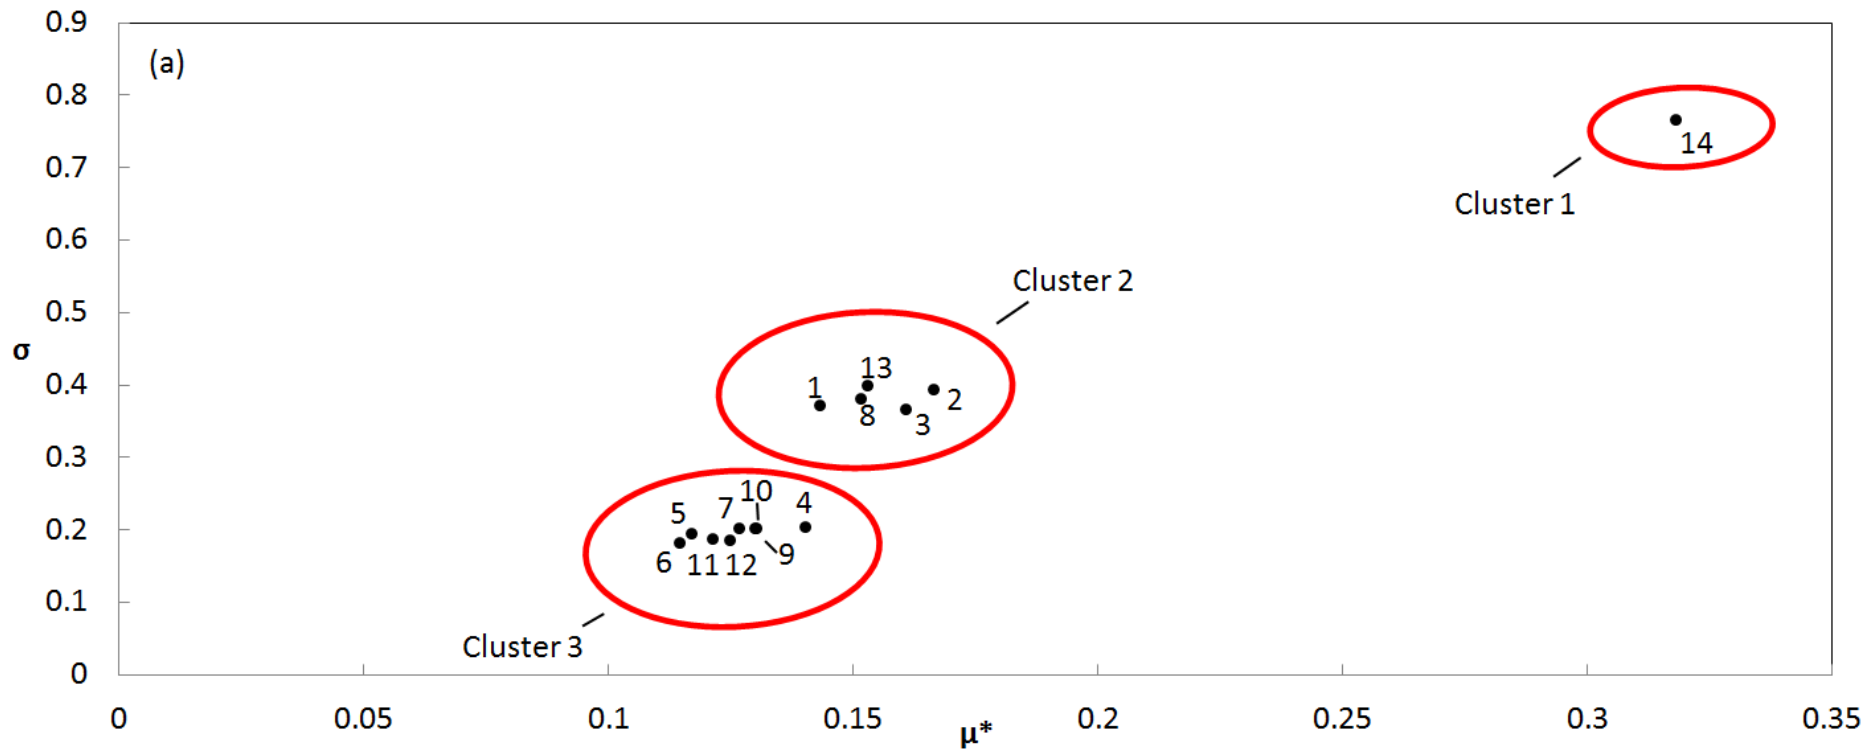

#	Parameters	VISSIM Default	Proposed Range
1	Average Standstill Distance (m)	2	[1, 3]
2	Additive Part of Desired Safety Distance	2	[0, 4]
3	Multiplicative Part of Desired Safety Distance	3	[1, 5]
4	Max Deceleration (Own) (m/s^2)	-4	[-6, -2]
5	Accepted Deceleration (Own) (m/s^2)	-1	[-1.5, -0.5]
6	-1 m/s^2 per Distance (Own) (m)	100	[50, 150]
7	Max Deceleration (Trailing) (m/s^2)	-3	[-5, -1]
8	Accepted Deceleration (Trailing) (m/s^2)	-1	[-1.5, -0.5]
9	-1 m/s^2 per Distance (Trailing) (m)	100	[50, 150]
10	Minimum Headway (m)	0.5	[0.3, 1]
11	Safety Distance Reduction Factor	0.6	[0, 1]
12	Max. Deceleration for Cooperative Braking (m/s^2)	-3	[-5, -1]
13	Lane Change Distance (m)	200	[150, 250]
14	Emergency Stop Distance (m)	5	[3, 7]

Travel Time Measurement in VISSIM

SA Results (1/2)

Plots of μ^* versus σ of the EE for the 14 parameters. The plots are separated into 3 clusters based on the K-Means Clustering.

SA Results (2/2)

Plots of μ versus σ of the EE for the 14 parameters. Lines in the figure correspond to $\mu = \pm 2\text{SEM}^*$

*SEM = Standard Error of the Mean = $\sigma / \sqrt{\text{sample size}}$

Parameters for Further Analysis

#	Parameters
1	Average Standstill Distance (m)
2	Additive Part of Desired Safety Distance
3	Multiplicative Part of Desired Safety Distance
8	Accepted Deceleration (Trailing) (m/s^2)
13	Lane Change Distance (m)
14	Emergency Stop Distance (m)

Conclusions

- Quasi-OTEE is an improvement to the EE method with much higher efficiency. In the case study, the time cost was reduced from 116 days to 3 days.
- Quasi-OTEE is a practical and efficient screening tool for computationally expensive microscopic traffic models, as well as other complex models in the wider scientific community.

Potential extensions:

- Converting this approach into a quantitative SA approach based on the same design and sampling process.
